1. In the present investigation, the independent variable was the use of a VAS to assess the perceived risk of injury due to the use of a VAS and the dependent variable was the use of a VAS to assess the perceived risk of injury due to the use of a VAS. The results of the study suggest that the use of a VAS to assess the perceived risk of injury due to the use of a VAS is a valid and reliable method of assessing the perceived risk of injury due to the use of a VAS. The results of the study suggest that the use of a VAS to assess the perceived risk of injury due to the use of a VAS is a valid and reliable method of assessing the perceived risk of injury due to the use of a VAS.

For instance, the principal component analysis of the 10 items used in the study revealed that the first principal component (eigenvalue = 4.36) explained 43.6% of the variance in the responses to the 10 items. The second principal component (eigenvalue = 1.86) explained 18.6% of the variance in the responses to the 10 items. The third principal component (eigenvalue = 1.14) explained 11.4% of the variance in the responses to the 10 items. The fourth principal component (eigenvalue = 0.84) explained 8.4% of the variance in the responses to the 10 items. The fifth principal component (eigenvalue = 0.64) explained 6.4% of the variance in the responses to the 10 items. The sixth principal component (eigenvalue = 0.44) explained 4.4% of the variance in the responses to the 10 items. The seventh principal component (eigenvalue = 0.34) explained 3.4% of the variance in the responses to the 10 items. The eighth principal component (eigenvalue = 0.24) explained 2.4% of the variance in the responses to the 10 items. The ninth principal component (eigenvalue = 0.14) explained 1.4% of the variance in the responses to the 10 items. The tenth principal component (eigenvalue = 0.04) explained 0.4% of the variance in the responses to the 10 items.
