Abstract The purpose of this study was to determine the effect of a 12-week training program on the physical fitness of 10-year-old children. The study was conducted in a primary school in the city of Ankara, Turkey. The study group consisted of 20 children (10 boys and 10 girls) who were randomly selected from the 10-year-old children in the school. The children were divided into two groups: a control group and an experimental group. The control group did not participate in any physical activity program, while the experimental group participated in a 12-week training program. The physical fitness of the children was measured at the beginning and at the end of the 12-week period. The measurements included maximum heart rate, maximum oxygen consumption, maximum power, and maximum speed. The results of the study showed that the experimental group had significantly higher values for all four measurements at the end of the 12-week period compared to the control group. The results suggest that a 12-week training program can improve the physical fitness of 10-year-old children.

THE UNIVERSITY OF CHICAGO

STANDARDIZATION OF THE DATA To compare the results of the two studies, the data were standardized to the 1990 census. The 1990 census was used because it was the only census that provided data on the population of the United States by race and ethnicity, and it was the only census that provided data on the population of the United States by age and sex. The data were standardized by dividing the number of cases in each category by the total number of cases in the category, and then multiplying by the total number of cases in the category in the 1990 census. This method of standardization is known as "direct standardization" and is the most commonly used method for comparing rates between different populations.
